

# Programming Technique II SECJ1023

Semester 2, 2022/2023

Faculty of Computing, UTM

### **Course Overview**

The course covers another concept of programming: Object-Oriented Programming (OOP)

### **Course Topics**

- Overview of Programming Paradigms
- Introduction to OOP
- Introduction to Classes and Objects
- Constructors and Destructors
- Class and Object Manipulations
- String Manipulations
- Associations, Aggregations and Compositions
- Inheritance
- Polymorphisms
- Exceptions and Templates
- Containers and Iterators

# 01: Introduction to Objectoriented Programming

Programming Technique II (SECJ1023)

Adapted from Tony Gaddis and Barret Krupnow (2016), Starting out with C++: From Control Structures through Objects

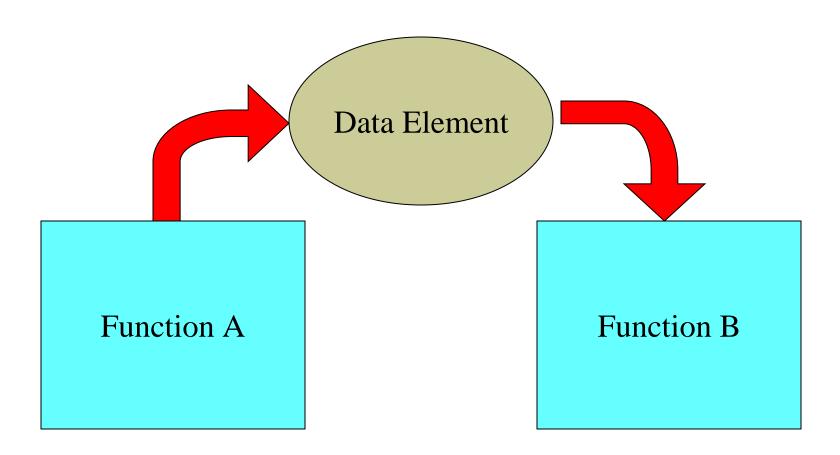

# Procedural Programming (PP)

- Traditional programming languages were procedural.
  - ◆ C, Pascal, BASIC, Ada and COBOL
- Programming in procedural languages involves choosing data structures (appropriate ways to store data), designing algorithms, and translating algorithm into code.
- In procedural programming, data and operations are separated.
- This methodology requires sending data to procedure/functions

## **Procedural Programming**

## **Functional Programming (FP)**

- FP is a programming paradigm where programs are constructed by applying and composing functions
- Functions are treated as first-class citizen. They can be:
  - bound to names
  - passed as parameters to other functions
  - returned from other functions

### FP uses declarative programming style

 expresses the logic of WHAT the program should accomplish without specifying how it should achieve that.

Note: PP and OOP use imperative programming style. This style focuses on describing HOW a program operates

# Comparison of FP to Imperative Programming

#### Example Problem:

Multiply all even numbers in an array by 10 and add them all, storing the final sum in the variable "result".

Both solution on the next slides are written in JavaScript, but with different programming paradigms

#### Traditional imperative loop

```
const numList = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10];
let result = 0;
for (let i = 0; i < numList.length; i++) {</pre>
  if (numList[i] % 2 === 0) {
    result += numList[i] * 10;
```

### Functional Programming with high-order functions

### **FP Concepts**

- High-order and Callback Functions
- Pure Functions
- Lambda Functions
- Currying
- Recursion
- Function composition

#### Further readings:

Functional programming

https://en.wikipedia.org/wiki/Functional\_programming

### A Comprehensive Look at Functional Programming (FP)

https://medium.com/swlh/a-comprehensive-look-at-functional-programming-fp-4a87629ecaed

### High-order functions

- An High-order function (HOF) is a functions that meet either one of these requirements:
  - It accepts other functions as parameters
  - It returns a function (this kind of HOF is called a factory function)
- The functions that are sent as parameters are called callback functions
- Note that the sent functions will be bound rather than called to (execute)

### **Function Binding**

#### A variable can hold a function

```
#include <iostream>
     using namespace std;
     double getNumber(){
          return 9.5;
     int main()
          auto f = getNumber(); // normal function call
          auto g = getNumber; // This is function binding, not a function call
11
12
          cout << f << endl;</pre>
13
          cout << g << endl;</pre>
          cout << g() << endl;</pre>
14
15
16
          system("pause");
17
18
          return 0;
     }
19
Output:
9.5
1
9.5
```

### Returning Functions from a Function

In the following example, getFunctionByOperator is a high-order function

```
#include <iostream>
     using namespace std;
2
     double add(double a, double b){return a + b;}
     double subtract(double a, double b){return a - b;}
     double multiply(double a, double b){return a * b;}
     double divide(double a, double b){return a / b;}
8
     typedef double(BinaryFunction)(double, double);
10
     BinaryFunction* getFunctionByOperator(char oper){
12
         switch (oper){
             case '+' : return add;
13
             case '-' : return subtract;
14
             case '*' : return multiply;
15
             case '/' : return divide;
16
17
18
         return NULL;
19
```

### Return Function from Another Function

```
int main(){
21
          auto f = getFunctionByOperator('+');
22
          BinaryFunction* g = getFunctionByOperator('*');
23
24
25
          cout << f(2,3) << endl;
          cout << f(12,5) << endl;
26
27
          cout << g(2,3) << endl;
28
          cout << g(12,5) << endl;</pre>
29
30
31
          system("pause");
          return 0;
32
33
```

#### Output:

### High-order Functions and Callbacks

In the following example, add and multiply are callback functions and doCalculation is a high-order function

```
#include <iostream>
     using namespace std;
     typedef double(BinaryFunction)(double, double);
     void doCalculation(double a, double b, BinaryFunction f)
         double r = f(a, b);
         cout << "Result: " << r << endl;</pre>
10
11
12
     double add(double a, double b){ return a + b;}
13
     double multiply(double a, double b){return a * b;}
14
     int main()
15
16
         doCalculation(1,2, add);
         doCalculation(5,4, multiply);
19
         system("pause");
20
21
         return 0;
22
```

#### Output:

Result: 3

Result: 20

### Practical Use Case of High-order Functions

#### To manipulate arrays

```
#include <iostream>
     using namespace std;
     void print(int item) { cout << item << endl; }</pre>
 4
 5
    void printOdd(int item){
 6
         if (item % 2){ cout << item << endl; }
 8
 9
10
     void forEach(const int list[], int size, void (*f)(int)){
11
         for (int i = 0; i < size; i++)
12
             f(list[i]);
13
14
```

### Practical Use Case of High-order Functions

```
15 \vee int main(){
          int numbers[] = {1, 2, 5, 6, 3};
16
17
          forEach(numbers, 5, print); // Print all numbers in the array
18
          cout << endl;</pre>
19
20
          forEach(numbers, 5, printOdd); // Print odd numbers
21
          cout << endl;</pre>
22
23
24
          // Print numbers greater than 3
          forEach(numbers, 5, [](int item){ if (item>3) cout << item << endl; }</pre>
25
26
27
          system("pause");
          return 0;
28
```

#### Lambda Functions

- Lambda functions are functions without names.
- They can be written inline (no need declaration)
- They cannot be re-used (i.e. they execute only once)
- Some use cases of Lambda functions:
  - Function binding
  - Passing functions as parameters to another function.
  - Returning a function from another.

# Lambda Function Example 1: Function Binding

 You can assign a variable with a function directly or inline (i.e., no need to declare the function first)

```
#include <iostream>
#include <string>
using namespace std;

Lambda function

int main()

auto plus = [](auto a, auto b){ return a + b;};

cout << "Integer plus: " << plus(20,1) << endl;
cout << "Number plus : " << plus(2.5,1.3) << endl;
cout << "String plus : " << plus(string("Hello "), string("World")) << endl;
cin.get();
return 0;
}</pre>
```

#### Output:

Integer plus: 21 Number plus: 3.8

String plus: Hello World

# Lambda Function Example 2: Passing functions as parameters

- A callback can be directly written to the high-order function (without having it defined first).
- This is called Lambda function (or Anonymous function, i.e. nameless or no name function)

```
#include <iostream>
     using namespace std;
     typedef double(BinaryFunction)(double, double);
     void doCalculation(double a, double b, BinaryFunction f)
         double r = f(a, b);
         cout << "Result: " << r << endl;</pre>
10
                                   Lambda function
11
     int main()
12
13
         doCalculation(1,2, [](double a, double b){ return a + b;}
14
15
         doCalculation(5,4, [](double a, double b){ return a * b;} );
16
         system("pause");
17
                                        Lambda function
         return 0;
18
19
```

#### Output:

Result: 3

Result: 20

# Lambda Function Example 3: Returning a function from another function

- In the following example, powerOf is a function factory (a function that returns another function).
- square, cube and squareRoot are functions generated from the function factory.

```
#include <iostream>
#include <cmath>
using namespace std;
auto powerOf(float exponent)
    return [exponent](float number) { return pow(number, exponent); };
int main()
                                    Lambda function
    auto square = powerOf(2);
    auto cube = powerOf(3);
    auto squareRoot = powerOf(0.5);
    cout << "Square: " << square(25) << endl;</pre>
    cout << "Cube: " << cube(2) << endl;</pre>
    cout << "Square Root: " << squareRoot(2) << endl;</pre>
    cin.get();
    return 0;
```

#### Output:

Square: 625 Cube: 8

Square Root: 1.41421

### Currying

- Currying is a technique from Functional Programming that transforms a function accepting multiple parameters into several functions accepting single parameter
- The translation looks something like this:

```
originalFunction(param1, param2, param3)
curriedFunction(param1)(param2)(param3)
```

- Currying is implemented by wrapping a function inside a function, i.e.,
   the function returns the other function.
- The parent function takes the first parameter and returns the function that takes the next parameter and this repeats until the last parameter.

### Currying

- From the previous example, there will be three function calls at the curriedFunction:
  - Call to the parent function, i.e., **curriedFunction** which takes param1 and returns another function (we call this function, a).

```
a = curriedFunction(param1)
```

• Call to the function **a** which takes param2 and returns another function (we call this function, **b**).

```
b = a(param2)
```

Call to the function b which takes param3 and returns the result.

```
result = curriedFunction(param3)
```

#### **Currying Example:**

```
#include <iostream>
using namespace std;
// Normal function to calculate volume of a cuboid
int volume(int width, int length, int height)
    return width * length * height;
// Curried version of the above function
auto curriedVolume(int width)
    return [width](int length) {
        return [width, length](int height){
            return width * length * height;
int main()
    cout << "Volume1: " << volume(2,5,10) << endl;</pre>
    cout << "Volume2: " << curriedVolume(2)(5)(10) << endl;</pre>
    auto a = curriedVolume(2); // a is a generated function
    auto b = a(5); // b is a generated function
    cout << "Volume3: " << b(10) << endl;</pre>
    cin.get();
    return 0;
```

#### Output:

Volume1: 100 Volume2: 100 Volume3: 100

#### Recursion

- Recursion is a technique that uses functions to call to themselves.
- Such functions are called recursive functions.
- A recursion instruction continues until another instruction prevents it.
- Iterations in PP paradigm are done with loops. In FP paradigm, mostly using recursion to perform repeating tasks.
- A recursion code normally consists two parts:
  - Recursion. Parts where the function calls to itself
  - Base case (or termination condition). To end the recursion.

#### **Recursion Example**

```
#include <iostream>
using namespace std;
// Function to sum up all numbers from m to n using regular loop
int sumNumbers(int m, int n)
    int sum = 0;
    for (int i = m; i \leq n; i \leftrightarrow )
        sum = sum + i;
    return sum;
// The recursion version of the above function
int recursiveSumNumbers(int m, int n)
    if (m = n)
                    Base case
        return m;
    return m + recursiveSumNumbers(m + 1, n);
int main()
                               Recursion case
    cout << "Sum1: " << sumNumbers(1,5) << endl;</pre>
    cout << "Sum2: " << recursiveSumNumbers(1,5) << endl;</pre>
    cin.get();
    return 0;
```

Output:

Sum1: 15 Sum2: 15

# **Object-Oriented Programming (OOP)**

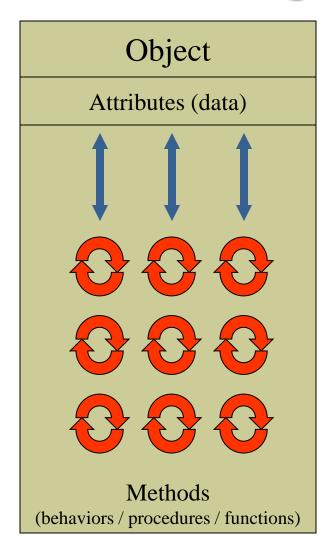

OOP is centred on objects rather than procedures / functions.

Objects are a melding of data and operations that manipulate that data.

Data in an object are known as properties or attributes.

Operations/functions in an object are known as methods.

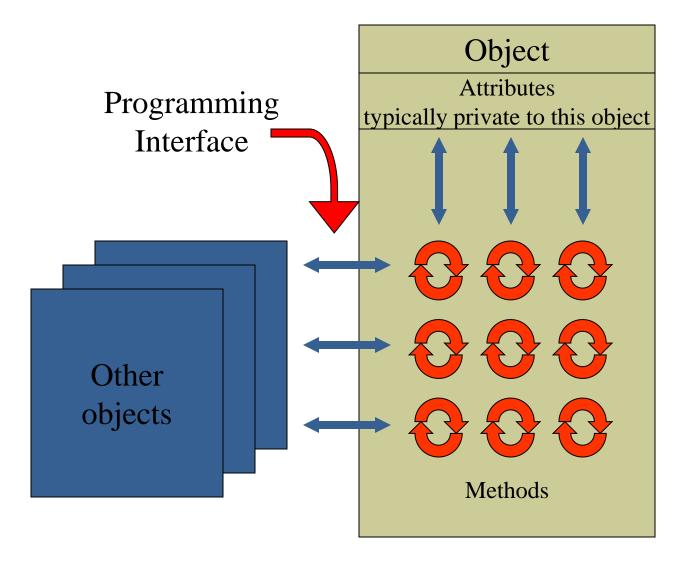

- Object-oriented programming combines data and methods via encapsulation.
- Data hiding is the ability of an object to hide data from other objects in the program
- Only object's methods should be able to directly manipulate its attributes
- Other objects are allowed to manipulate object's attributes via the object's methods.
- This indirect access is known as a programming interface

- Object-oriented programming combines data and methods via encapsulation.
- Data hiding is the ability of an object to hide data from other objects in the program
- Only object's methods should be able to directly manipulate its attributes
- Other objects are allowed to manipulate object's attributes via the object's methods.
- This indirect access is known as a programming interface

### **OOP Principles: Classes**

A class is the template or mould or blueprint from which objects are actually made.

A class encapsulates the attributes and actions that characterizes a certain type of object.

### **OOP Principles: Objects**

Classes can be used to instantiate as many objects as are needed.

Each object that is created from a class is called an instance of the class.

A program is simply a collection of objects that interact with each other to accomplish a goal.

### **Classes and Objects**

The *Car* class defines the attributes and methods that will exist in all objects that are instances of the class.

Car class

Kancil object

The Kancil object is an instance of the Car class.

The Nazaria object is an instance of the Car class.

Nazaria object

### **OOP Principles: Encapsulation**

Encapsulation is a key concept in working with objects:
Combining attributes and methods in one package and hiding the implementation of the data from the user of the object.

### Encapsulation:

Attributes/data

+

Methods/functions = Class

#### **Example:**

a car has attributes and methods below.

#### Car

Attributes: model, cylinder capacity

*Methods:* move, accelerate

## **OOP Principles: Data Hiding**

- ② Data hiding ensures methods should not directly access instance attributes in a class other than their own.
- Programs should interact with object attributes only through the object's methods.
- Data hiding is important for several reasons.
  - It protects attributes from accidental corruption by outside objects.
  - ◆ It hides the details of how an object works, so the programmer can concentrate on using it.
  - ◆ It allows the maintainer of the object to have the ability to modify the internal functioning of the object without "breaking" someone else's code.

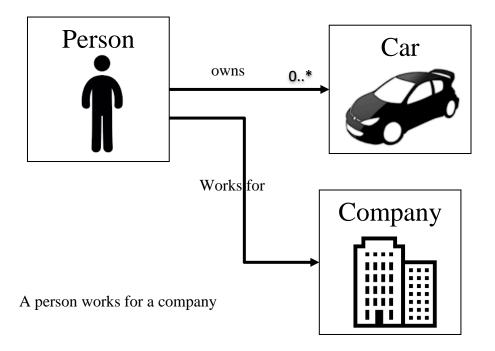

## **OOP Principles: Associations**

- Association: relates classes to each other through their objects.
- Association can be, one to one, one to many, many to one, or many to many relationships.

### **Example:**

A person can own several cars

## **OOP Principles: Inheritance**

- Inheritance is the ability of one class to extend the capabilities of another.
  - it allows code defined in one class to be reused in other classes

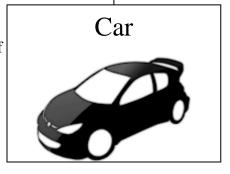

## **Example:**

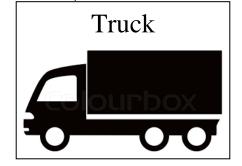

Vehicle represents all of the generic attributes and methods of a vehicle.

Vehicle
Vehicle is the parent class.

"is-a" relationship

Car and Truck are Specialized versions of a Vehicle.

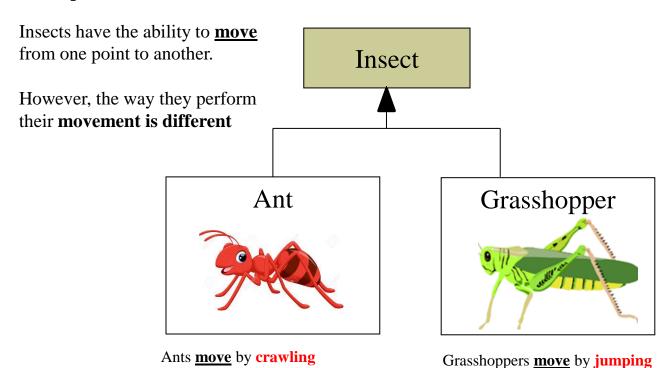

Car and Truck are child classes of Vehicle.

## **OOP Principles: Polymorphism**

Polymorphism is the ability of objects performing the same actions differently.

## **Example:**

## Self-test: Introduction to Object Oriented Programming

- State the differences between procedural programming and Object Oriented Programming.
- What is an Object and what is a Class? What is the difference between them?
- What is an Attribute?
- What is a Method?
- What is encapsulation? How it relates to data hiding?
- What is association?
- What is inheritance? How it relates to polymorphism?

# The Unified Modeling Language

Programming Technique II (SCSJ1023)

Adapted from Tony Gaddis and Barret Krupnow (2016), Starting out with C++: From Control Structures through Objects

# The Unified Modelling Language

UML stands for Unified Modelling Language.

The UML provides a set of standard diagrams for graphically depicting object-oriented systems

# **UML Class Diagram**

A UML diagram for a class has three main sections.

Class name goes here 

Member variables are listed here 

Member functions are listed here

## **Example: A Rectangle Class**

A UML diagram for a class has three main sections.

# Rectangle width length setWidth() setLength() getWidth() getLength() getArea()

```
class Rectangle
   private:
      double width;
      double length;
   public:
      bool setWidth(double);
      bool setLength(double);
      double getWidth() const;
      double getLength() const;
      double getArea() const;
```

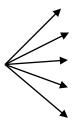

## **UML Access Specification Notation**

In UML you indicate a private member with a minus (-) and a public member with a plus(+).

These member variables are private.

These member functions are public.

## Rectangle

- width
- length
- + setWidth()
- + setLength()
- + getWidth()
- + getLength()
- + getArea()

## **UML Data Type Notation**

To indicate the data type of a member variable, place a colon followed by the name of the data type after the name of the variable.

- width : double

- length : double

## **UML Parameter Type Notation**

To indicate the data type of a function's parameter variable, place a colon followed by the name of the data type after the name of the variable.

+ setWidth(w : double)

# **UML Function Return Type Notation**

To indicate the data type of a function's return value, place a colon followed by the name of the data type after the function's parameter list.

+ setWidth(w : double) : void

# The Rectangle Class

## Rectangle

- width: double
- length : double
- + setWidth(w : double) : bool
- + setLength(len : double) : bool
- + getWidth(): double
- + getLength(): double
- + getArea(): double

# Showing Constructors and Destructors

No return type listed for constructors or destructors

Constructors

Destructor

## InventoryItem

- description : char\*
- cost : double
- units : int
- createDescription(size : int, value : char\*) : void
- + InventoryItem():
- + InventoryItem(desc : char\*) :
- + InventoryItem(desc : char\*,
  - c: double, u:int):
- + ~InventoryItem():
- + setDescription(d : char\*) : void
- + setCost(c : double) : void
- + setUnits(u : int) : void
- + getDescription() : char\*
- + getCost() : double
- + getUnits(): int
